

What I Did

To complete the activity, I began by ensuring that Homebrew was installed and fully updated on my Mac system. I verified this by running the brew update command, which confirmed that my package manager was functioning properly. Once updated, I proceeded to install the Azure Command-Line Interface (CLI) using the command brew install azure-cli. After installation, I confirmed that Azure CLI was correctly installed by running az --version, which displayed the currently installed version and associated dependencies. Following this, I initiated the login process with az login, which opened a browser window prompting me to sign in using my Full Sail credentials. Upon successful login, a confirmation message and authentication token were displayed in the terminal. In the final step, I ran az storage account list to verify access to my Azure storage resources. One challenge I encountered was a permissions error during the az login attempt, which I resolved by ensuring that my default browser allowed popups and by clearing old login tokens from previous sessions.

What I Learned

Through this activity, I learned how to set up and use the Azure CLI on a Mac system via Homebrew, a key skill for managing Azure resources efficiently from the command line. I also gained experience in using terminal-based authentication methods with institutional credentials, which is essential for secure enterprise-level access. Additionally, I developed a better understanding of how to validate successful installations and logins using version checks and storage account listings. This exercise helped reinforce the importance of keeping development tools updated and highlighted practical troubleshooting strategies, such as adjusting browser settings for login authentication and ensuring account permissions are correctly configured in Azure.

Summary

This activity provided hands-on experience in configuring and verifying access to Azure resources using the Azure CLI on a Mac. The process began with installing Homebrew and Azure CLI, continued with authenticating through institutional credentials using az login, and concluded with confirming access to storage accounts via the az storage account list command. Along the way, I encountered and resolved a login permissions issue, deepening my problem-solving skills in a cloud-based context. Overall, this exercise enhanced my understanding of CLI-based cloud management and prepared me to perform essential Azure administrative tasks confidently.
