

What I Did

To complete this Azure CLI activity, I began by verifying my credentials and identifying the appropriate storage account. Running `az storage account list` provided me with a JSON response that included the relevant storage account with the name "kwaldenweb" and its resource group "NetworkWatcherRG." I confirmed that the account was of the required "StorageV2" kind. For Step 2, I downloaded the provided zip file to my home directory and unzipped it, revealing the script file `DTYo-assignment-3.2.sh`. I edited lines 11 and 12 of the script to set the variables `RES=NetworkWatcherRG` and `STOR=kwaldenweb`, then verified that the script had executable permissions using `ls -al`. In Step 3, I executed the modified script and verified successful deployment by running the command `az storage account show -n kwaldenweb -g NetworkWatcherRG --query "primaryEndpoints.web" --output tsv`. I copied the resulting URL into my browser, where I confirmed the site had deployed by checking for the expected web content. Throughout the process, my main issue was initially receiving a "WebContentNotFound" error, which I resolved by confirming the static website hosting feature had been enabled for the storage account via the Azure portal.

What I Learned

This exercise deepened my understanding of Azure CLI operations, particularly around managing storage accounts and deploying static websites. I learned how to query storage account details via JSON output, identify key configuration parameters like `kind` and `resourceGroup`, and how to use those values in shell scripting to automate deployment tasks. I also learned the importance of file permissions when executing shell scripts and how to verify that using the `ls -al` command. Additionally, I gained practical insight into troubleshooting deployment issues, such as missing web content due to an unconfigured static hosting endpoint. This experience reinforced the value of careful validation at each step of a deployment workflow.

Summary

This activity provided a hands-on opportunity to practice deploying a static website using the Azure CLI and a custom shell script. I navigated the process from identifying the correct storage account to editing and executing a deployment script, and finally verifying the site through a public endpoint. Through this workflow, I became more comfortable with Azure's CLI environment, shell scripting integration, and troubleshooting static site deployments. The task highlighted both the technical steps required and the importance of accurate configuration, reinforcing foundational knowledge of cloud-based infrastructure deployment and automation.
